Abstract
Objectives: The aim of this study has been to investigate serum activities of liver enzymes in workers exposed to sub-TLV levels of dimethylformamide (DMF).
Material and Methods: Seventy-two workers and 72 healthy controls participated in the study. All subjects underwent complete physical examinations and abdominal ultrasound examination. Serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and c-glutamyl transpeptidase (c-GT) were determined by an auto-chemistry analyzer. The data of airborne concentrations of DMF was obtained from the local Center of Disease Control and Prevention. The level of urine N-acetyl-S-(N-methylcarbamoyl)cysteine (AMCC) was measured by means of high-performance liquid chromatography.

Results: Time weighted average (TWA) concentration of the DMF in workplace was 18.6 (range: 9.8–36.2) mg/m3. The concentration of the AMCC in workers’ urine was 28.32 (range: 1.8–58.6) mg/l and 9 workers’ AMCC exceeded the biological exposure index (40 mg/l). Thirty-one workers reported gastrointestinal symptoms (abdominal pain, nausea, anorexia) and 10 workers reported headache, dizziness and/or palpitation in the exposed group. Serum analysis revealed that both the mean of serum activities of liver enzymes (ALT, AST and c-GT) and the percentage of workers with abnormal liver function were significantly higher in the exposed group as compared to the controls.

Conclusions: Dimethylformamide can cause liver damage even if air concentration is in the sub-threshold limit value (sub-TLV) level. The protection of skin contact against the exposure to the DMF might be a critical issue as far as the occupational health is concerned.

INTRODUCTION
The dimethylformamide (DMF) is miscible with water and most organic solvents and is widely used in industry, especially in factories handling polyurethane materials and acrylic fibers [1]. It is a well-recognized fact that overexposure to the DMF could result in hepatotoxicity. China is the largest producer and consumer of the DMF in the world. The environmental airborne DMF is a good index to evaluate the general situation in the workplaces. Regular air monitoring of the DMF is required by the
government. The current threshold limit value (TLV) for the DMF in the workplace is 20 mg/m³ (8 h-TWA (time-weighted average)) in China. Multi-intervention measures have contributed to the substantial decrease in the concentration of the DMF in the workplaces [2]. However, frequently reported cases have indicated that hepatotoxicity caused by the DMF exposure is still a concern in China [3,4]. Biological monitoring is a precise approach for the occupational exposure assessment and prevention of adverse effects. The N-acetyl-S-(N-methylcarbamoyl) cysteine (AMCC), a metabolite of the DMF, has long half-life of 23–34 h and accumulates in the human body and has been used to evaluate the DMF exposure [5]. In this study, a cross-sectional study has been undertaken to study serum activities of liver enzymes in workers exposed to sub-TLV levels of the DMF.

MATERIAL AND METHODS
The study subjects worked in a factory that manufactures synthetic leather by mixing the DMF, resin and other chemicals. Seventy-two subjects who were occupationally exposed to the DMF with minimum of 1 year were recruited for this study. They were sex and age matched with 72 control subjects who had no exposure to the DMF. Pregnant workers, and workers with continuous medication during the last 2 months, hepatic-related diseases, hepatitis B virus (HBV) and alcohol consumption exceeding 25 g/day were excluded from this study. Characteristics of workers are shown in the Table 1. Each subject gave a written informed consent and the local ethics committee approved the study.

Each subject was interviewed by a physician. All subjects underwent complete physical examinations and abdominal ultrasound examination. Serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and c-glutamyl transpeptidase (c-GT) were determined by an auto-chemistry analyzer (Olympus AU640, PA, USA). The surface antigen of the hepatitis B virus (HBsAg) was measured by ELISA to confirm the lack of HBV carriers.

The data of airborne concentrations of DMF was obtained from the local Center of Disease Control and Prevention (CDC) which monitors the workplace 4 times per year. The level of urine N-acetyl-S-(N-methylcarbamoyl)cysteine (AMCC) was measured by high-performance liquid chromatography (HPLC) with a photodiode array (PDA) detector (Waters 2695, MA, USA). In brief, urine samples were filtered by solid phase extraction and the separation was carried out on a C18 reserved-phase column. The coefficients of variation were below 3%. The limit of detection was 0.4 mg/l. The calibration curve was linear up to 50 mg/l.

Data was analyzed using the Student’s t-test and Chi² by the SPSS statistical package (v. 11.0). Results were expressed in terms of means ± standard error of the mean (M±SEM).

RESULTS
The data from the local CDC indicated the TWA concentration of the DMF in workplaces to stand at 18.6 mg/m³ (range: 9.8–36.2 mg/m³), which was below TLV. However, the wide fluctuation of concentrations indicated the possibility of occasional overexposure. The concentration of the AMCC in workers’ urine was 28.32 mg/l (range: 1.8–58.6 mg/l) and 9 workers’ AMCC exceeded the biological exposure index (Table 1).
who have found that the DMF can cause liver function alternations even if air concentration of the DMF is kept below the permissible concentration-time weighed average (PC-TWA) [6]. Luo et al. also reported 27% of abnormal liver function tests among workers with the DFM exposure kept below 10 ppm [7]. Therefore, liver functions of workers exposed to sub-TLV levels of the DMF deserve further study, especially in Chinese population.

Nine workers’ urine AMCC concentrations exceed the limits (40 mg/l) notwithstanding the exposure to the DMF air concentrations as kept below TLVs, which indicates skin absorption that might occur in the workers. The DMF dermal exposure plays a great role in the DMF absorption or accidental skin contamination because workers may be exposed to the DMF repeatedly. It has been reported that the DMF exposure through skin contact is related to a great degree to the DMF-induced total body burden [8–10]. In addition, genetic polymorphism of the DMF metabolizing enzymes might cause elevated urine AMCC.

**DISCUSSION**

High prevalence of liver function abnormalities was found in workers exposed to sub-TLV level of the DMF. Since those knowing non-occupational factors were excluded from this study, it is supposed that higher liver enzyme levels in the workers in this study are related to the DMF exposure. The DMF is a well-known hepatotoxic chemical. However, whether a lower level of the DMF exposure induces liver damage is still a controversy. Our findings are in agreement with the observations of Qian et al, who have found that the DMF can cause liver function alternations even if air concentration of the DMF is kept below the permissible concentration-time weighed average (PC-TWA) [6]. Luo et al. also reported 27% of abnormal liver function tests among workers with the DFM exposure kept below 10 ppm [7]. Therefore, liver functions of workers exposed to sub-TLV levels of the DMF deserve further study, especially in Chinese population. Nine workers’ urine AMCC concentrations exceed the limits (40 mg/l) notwithstanding the exposure to the DMF air concentrations as kept below TLVs, which indicates skin absorption that might occur in the workers. The DMF dermal exposure plays a great role in the DMF absorption or accidental skin contamination because workers may be exposed to the DMF repeatedly. It has been reported that the DMF exposure through skin contact is related to a great degree to the DMF-induced total body burden [8–10]. In addition, genetic polymorphism of the DMF metabolizing enzymes might cause elevated urine AMCC.

**CONCLUSIONS**

In conclusion, we have found significantly abnormal serum activities of liver enzymes in workers with sub-TLV level of the DMF exposure. The protection of skin against the
